Winter Semester 2017

WEEK 6

Python Programming: BioPython

Genetics 101

git – Version Control

git – Version Control

```
$ git fetch    # should download files without merging remote and local files
```

```
$ git pull    # downloads remote and merges these with the local files
```

What should you do?

```
$ git stash    # run the stash command in your folder to set your modified aside
```

```
$ git pull    # pulls files from the cloud into your local folder and merges remote with local;  
              # this may overwrite changes you made in your local folder
```

```
$ git stash pop  # overwrite files that came from upstream with the files you set aside earlier
```

```
$ git stash show  # shows the files that were reverted to your local files
```

Install BioPython – we will need it later

```
sudo apt-get install python-biopython
```

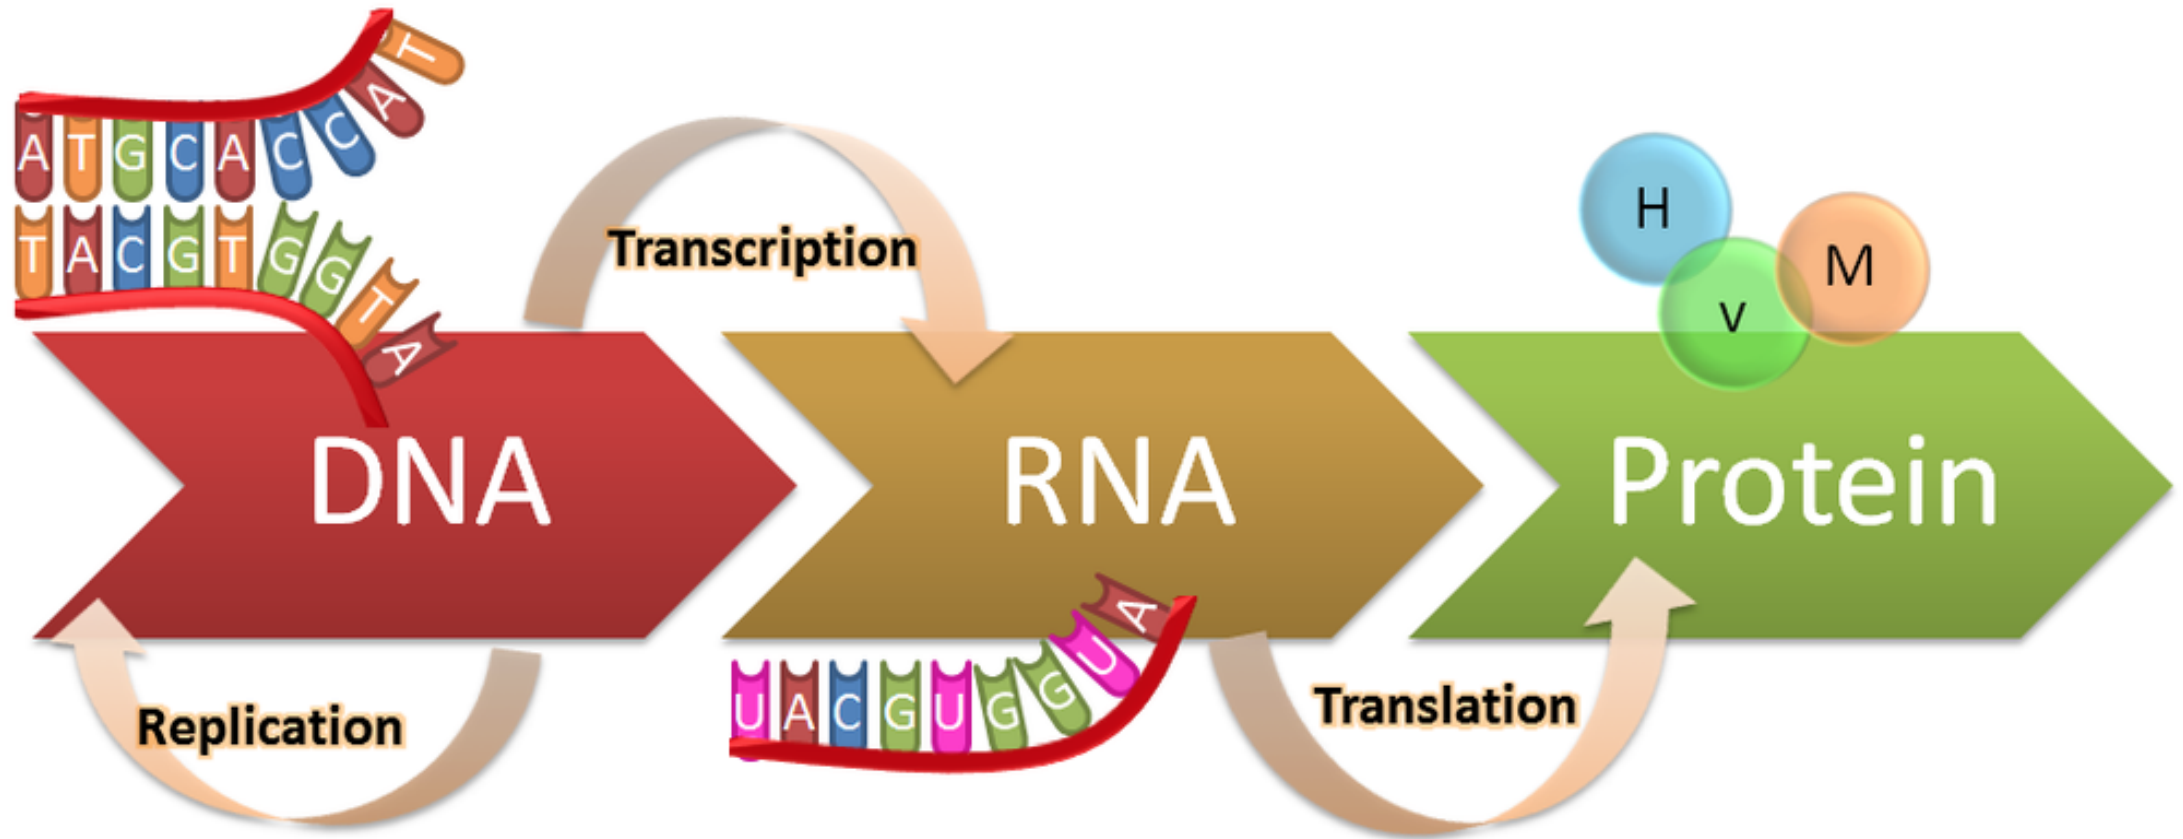

Reading a File using a While Loop

```
Line = File.readline()  
while Line:  
    do something  
    Line = File.readline()
```

DNA

Translation

The translation process incorporates 20 different amino acids in the precise sequence dictated by the three-base codons built from an alphabet of four bases. The process in the ribosome builds the polypeptide chains that will become proteins.

BioPython – let's work through some examples
